Notation	Description
$n, p, k$	number of observations, variables, embedding dimension, respectively
$\mathbf{X}, \mathbf{x}$	$p$ -dimensional data (population, sample)
$\mathbf{y}$	$k$ -dimensional layout
$P$	orthonormal basis, generating a $d$ -dimensional linear projection of $p$ -dimensional data
$T$	true model
$g$	functional mapping from $p$ -D to $k$ -D, especially as prescribed by NLDR
$\theta$	(Hyper-) parameters for NLDR method
$r$	ranges of the embedding components
$C^{(j)}$	$j$ -dimensional bin centers
$(b_1, b_2)$	number of bins in each direction
$(a_1, a_2)$	binwidths, distance between centroids in each direction
$(s_1, s_2)$	starting coordinates of the hexagonal grid
$q$	buffer to ensure hexgrid covers data, proportion of data range, 0-1
$m$	number of non-empty bins
$b$	number of hexagons in the grid
$h$	hexagonal id
$l$	side length
$A$	area
$n_h$	bin count
$w_h$	standardised bin counts

Table 1: Summary of notation for describing new methodology.

# 1 Generating the nonlinear clusters data

Figure 1: Two projections of the  $p$ - $D$  true model overlaying the data are shown in a, b.

## 2 Computing hexagon grid configurations

Given range of embedding component,  $r_2$ , number of bins along the x-axis,  $b_1$ , and buffer proportion,  $q$ , hexagonal starting point coordinates,  $s_1 = -q$ , and  $s_2 = -qr_2$ . The purpose is to find width of the hexagon.  $a_1$ , and number of bins along the y-axis,  $b_2$ .

Geometric arguments give rise to the following constraints.

$\min a_1$  s.t.

$$s_1 - \frac{a_1}{2} < 0, \tag{1}$$

$$s_1 + (b_1 - 1) \times a_1 > 1, \tag{2}$$

$$s_2 - \frac{a_2}{2} < 0, \quad (3)$$

$$s_2 + (b_2 - 1) \times a_2 > r_2. \quad (4)$$

Since  $a_1$  and  $a_2$  are distances,

$$a_1, a_2 > 0.$$

Also,  $(s_1, s_2) \in (-0.1, -0.05)$  as these are multiplicative offsets in the negative direction.

Equation 1 can be rearranged as,

$$a_1 > 2s_1$$

which given  $s_1 < 0$  and  $a_1 > 0$  will *always* be true. The same logic follows for Equation 3

and substituting  $a_2 = \sqrt{3}a_1/2$ , and  $s_2 = -qr_2$  to Equation 3 can be written as,

$$a_1 > -\frac{4}{\sqrt{3}}qr_2$$

Also, substituting  $a_2 = \sqrt{3}a_1/2$ ,  $s_2 = -qr_2$  and rearranging Equation 4 gives:

$$a_1 > \frac{2(r_2 + qr_2)}{\sqrt{3}(b_2 - 1)}. \quad (5)$$

Similarly, substituting  $s_1 = -q$  Equation 2 becomes,

$$a_1 > \frac{(1+q)}{(b_1-1)}. \quad (6)$$

This is a linear optimization problem. Therefore, the optimal solution must occur on a vertex. So, by setting Equation 5 equals to Equation 6 gives,

$$\frac{2(r_2 + qr_2)}{\sqrt{3}(b_2-1)} = \frac{(1+q)}{(b_1-1)}.$$

After rearranging this,

$$b_2 = 1 + \frac{2r_2(b_1-1)}{\sqrt{3}}$$

and since  $b_2$  should be an integer,

$$b_2 = \left\lceil 1 + \frac{2r_2(b_1-1)}{\sqrt{3}} \right\rceil. \quad (7)$$

Furthermore, with known  $b_1$  and  $b_2$ , by considering Equation 2 or Equation 4 as the *binding* or *active constraint*, can compute  $a_1$ .

If Equation 2 is active, then,

$$\frac{(1+q)}{(b_1-1)} < \frac{2(r_2 + qr_2)}{\sqrt{3}(b_2-1)}.$$

Rearranging this gives,

$$r_2 > \frac{\sqrt{3}(b_2-1)}{2(b_1-1)}.$$

Therefore, if this equality is true, then

$$a_1 = \frac{(1+q)}{(b_1-1)},$$

otherwise,

$$a_1 = \frac{2r_2(1+q)}{\sqrt{3}(b_2-1)}.$$

### 3 Binning the data

Points are assigned to the bin they fall into based on the nearest centroid. If a point is equidistant from multiple centroids, it is assigned to the centroid with the smallest bin ID.

Figure 2: Binning the data. Points are assigned to the nearest centroid. If a point is equidistant from multiple centroids, assigned to the centroid with the smallest bin ID.

## 4 Area of a hexagon

The area of a hexagon is defined as  $A = 3\sqrt{3}l^2/2$ , where  $l$  is the side length of the hexagon.

$l$  can be computed using  $a_1$  and  $a_2$ .

Figure 3: The components of the right triangle illustrating notation.

By applying the Pythagorean theorem, we obtain,

$$l^2 = \left(\frac{a_1}{2}\right)^2 + \left(\frac{a_2 - l}{2}\right)^2.$$

Next, rearranging the terms, we get,

$$l^2 - \left(\frac{a_2 - l}{2}\right)^2 = \left(\frac{a_1}{2}\right)^2,$$

$$\left[l - \left(\frac{a_2 - l}{2}\right)\right] \left[l + \left(\frac{a_2 - l}{2}\right)\right] = \left(\frac{a_1}{2}\right)^2,$$

$$3l^2 + 2a_2l - (a_1^2 + a_2^2) = 0.$$

Finally, by solving the quadratic equation, we compute,

$$l = \frac{-2a_2 \pm \sqrt{4a_2^2 - 24[-(a_1^2 + a_2^2)]}}{6},$$

$$l = \frac{-a_2 \pm \sqrt{a_2^2 - 6[-(a_1^2 + a_2^2)]}}{3},$$

where  $l > 0$ .

## 5 Single-cell gene expression: comparison with results of scDEED recommendations

As we were writing this paper [Xia et al. \(2023\)](#) appeared proposing a new method called scDEED helping to assess the validity of a 2- $D$  embedding. scDEED calculates a reliability score for each cell embedding based on the similarity between the cell’s 2- $D$  embedding neighbors and its neighbors prior to embedding. A low reliability score suggests a dubious embedding. It can help in the deciding on optimal hyper-parameters. Here we illustrate how our method compares with the results from scDEED.

Note that [Xia et al. \(2023\)](#) uses a different subset from the PBMC dataset used by [Chen et al. \(2024\)](#), shown by us in the main paper example, which is why this comparison is shown here and not in the main paper. Their data contains 31,021 cells including cell type labels, and the gene expression levels were in the unit of log-transformed UMI count per 10,000. They focused on three sequencing methods (inDrops, DropSeq, and SeqWell) and four common cell types Cytotoxic T cell, CD4+T cell, CD14+ Monocyte, and B cell. Pre-processing follows the process in [Xia et al. \(2023\)](#) again using the Human Peripheral Blood Mononuclear Cells (PBMC) data.

For illustration purposes, we only selected cells generated with inDrops ( $n = 5858$  cells) and UMAP and tSNE cell embeddings. Also, [Xia et al. \(2023\)](#) used first 9 principal components to generate the UMAP and tSNE. The objective is to assess the optimized layout by scDEED, and if it does not accurately represent the three clusters with small separations of the PBMC dataset, then select a reasonable 2- $D$  layout.

The layout a (Figure 4) is generated from the hyper-parameters suggested by [Chen et al. \(2024\)](#), and the layout b (Figure 4) is with suggested hyper-parameters by scDEED to be more accurate. The layout a and b contain 46 and 83 dubious cells respectively.

Figure 4: Assessing which of the two layouts with UMAP and tSNE with different hyperparameter setting ( $n\_neighbors$ : 30,  $min\_dist$ : 0.3 (red);  $n\_neighbors$ : 30 (blue)) on the PBMC data is the better representation using RMSE for varying binwidth ( $a_1$ ). Colour used for the lines and points in the top plot and in the scatterplots represents UMAP and tSNE layouts (a, b). Of the two, layout b is optimal across all binwidths making it the best choice.

The RMSE vs binwidth ( $a_1$ ) plot (Figure 4) illustrates that our approach would suggest that scDEED is correct here, that layout b is more accurately reflecting the cluster structure in the PBMC data.

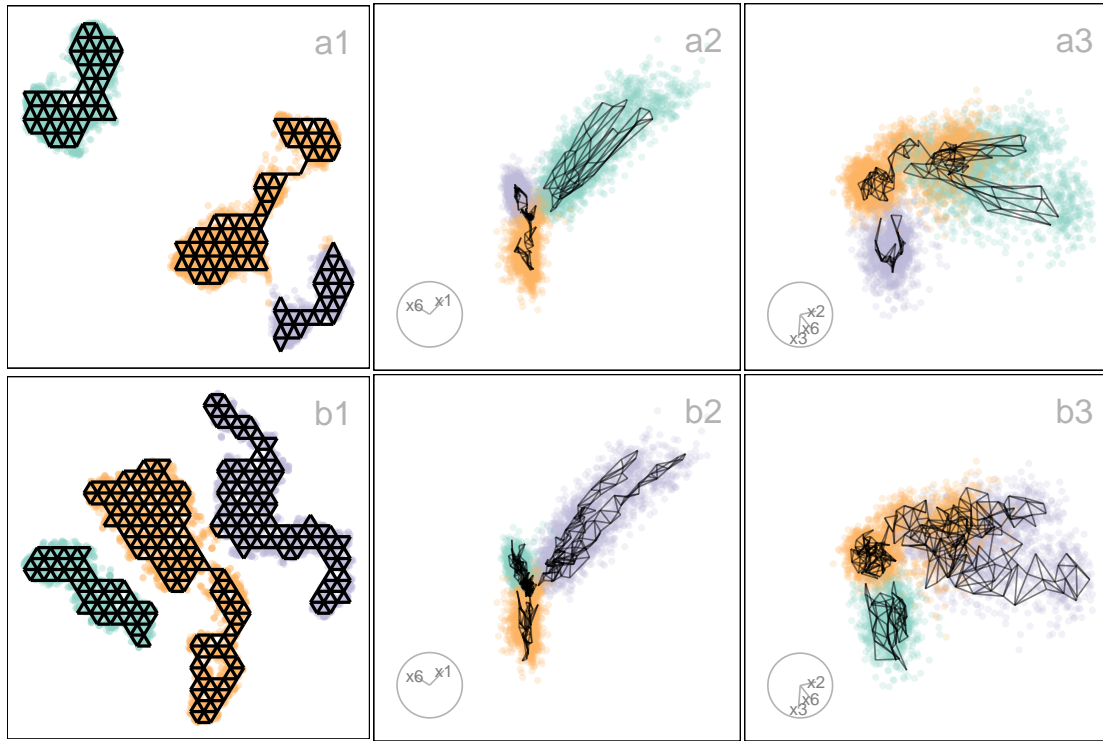

Figure 5: Compare the published 2- $D$  layout (Figure 4 a) and the 2- $D$  layout selected (Figure 4 b) by RMSE plot (Figure 4) from tSNE and UMAP with default hyper-parameters. The PBMC data ( $n = 5858$ ) has three clusters in 9- $D$ , where three clusters are close. Two 2- $D$  projection from a tour on 9- $D$  of the model fit with Figure 4 a ( $a_1 = 0.04$ ,  $b = 900/179(30, 30)$ ) shows three-well separated clusters with big separations. On the other hand, the model fit with Figure 4 b ( $a_1 = 0.04$ ,  $b = 1110/317(30, 37)$ ) shows three-well separated clusters with small separations. Therefore, Figure 4 b is more reasonable than Figure 4 a. Videos of the langevitour animations are available at [https://youtu.be/0cKX\\_HG\\_n0k](https://youtu.be/0cKX_HG_n0k) and <https://youtu.be/KhJvsRtaX04> respectively.
