Abstract

Notation	Description
n, p, k	number of observations, variables, embedding dimension, respectively
$oldsymbol{X},oldsymbol{x}$	p-dimensional data (population, sample)
y	k-dimensional layout
P $T$	orthonormal basis, generating a $d$ -dimensional linear projection of $p$ -dimensional data true model
1	
g	functional mapping from $p$ - $D$ to $k$ - $D$ , especially as prescribed by NLDR
heta	(Hyper-) parameters for NLDR method
r	ranges of the embedding components
$C^{(j)}$	j-dimensional bin centers
$(b_1,b_2)$	number of bins in each direction
$(a_1,a_2)$	binwidths, distance between centroids in each direction
$(s_1,\ s_2)$	starting coordinates of the hexagonal grid
q	buffer to ensure hexgrid covers data, proportion of data range, 0-1
m	number of non-empty bins
b	number of hexagons in the grid
h	hexagonal id
l	side length
<u>A</u>	area

Table 1: Summary of notation for describing new methodology.

## 1 Computing hexagon grid configurations

Given range of embedding component,  $r_2$ , number of bins along the x-axis,  $b_1$ , and buffer proportion, q, hexagonal starting point coordinates,  $s_1 = -q$ , and  $s_2 = -q \times r_2$ . The purpose is to find width of the hexagon.  $a_1$ , and number of bins along the y-axis,  $b_2$ .

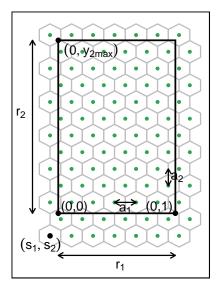

Figure 1: The components of the hexagon grid illustrating notation.

Geometric arguments give rise to the following constraints.

 $\min\,a_1\text{ s.t.}$ 

$$s_1 - \frac{a_1}{2} < 0, \tag{1}$$

$$s_1 + (b_1 - 1) \times a_1 > 1, (2)$$

$$s_2 - \frac{a_2}{2} < 0, \tag{3}$$

$$s_2 + (b_2 - 1) \times a_2 > r_2. \tag{4}$$

Since  $a_1$  and  $a_2$  are distances,

$$a_1, a_2 > 0.$$

Also,  $(s_1, s_2) \in (-0.1, -0.05)$  as these are multiplicative offsets in the negative direction.

Equation 1 can be rearranged as,

$$a_1 > 2s_1$$

which given  $s_1<0$  and  $a_1>0$  will always be true. The same logic follows for Equation 3 and substituting  $a_2=\frac{\sqrt{3}}{2}a_1$ , and  $s_2=-q\times r_2$  to Equation 3 can be written as,

$$a_1 > -\frac{4}{\sqrt{3}}qr_2$$

Also, substituting  $a_2=\frac{\sqrt{3}}{2}a_1,\,s_2=-q\times r_2$  and rearranging Equation 4 gives:

$$a_1 > \frac{2(r_2 + qr_2)}{\sqrt{3}(b_2 - 1)}. (5)$$

Similarly, substituting  $s_1=-q$  Equation 2 becomes,

$$a_1 > \frac{(1+q)}{(b_1-1)}. (6)$$

This is a linear optimization problem. Therefore, the optimal solution must occur on a vertex. So, by setting Equation 5 equals to Equation 6 gives,

$$\frac{2(r_2+qr_2)}{\sqrt{3}(b_2-1)}=\frac{(1+q)}{(b_1-1)}.$$

After rearranging this,

$$b_2 = 1 + \frac{2r_2(b_1 - 1)}{\sqrt{3}}$$

and since  $b_2$  should be an integer,

$$b_2 = \left\lceil 1 + \frac{2r_2(b_1 - 1)}{\sqrt{3}} \right\rceil. \tag{7}$$

Furthermore, with known  $b_1$  and  $b_2$ , by considering Equation 2 or Equation 4 as the *binding* or *active constraint*, can compute  $a_1$ .

If Equation 2 is active, then,

$$\frac{(1+q)}{(b_1-1)}<\frac{2(r_2+qr_2)}{\sqrt{3}(b_2-1)}.$$

Rearranging this gives,

$$r_2>\frac{\sqrt{3}(b_2-1)}{2(b_1-1)}.$$

Therefore, if this equality is true, then  $a_1 = \frac{(1+q)}{(b_1-1)}$ , otherwise,  $a_1 = \frac{2r_2(1+q)}{\sqrt{3}(b_2-1)}$ .

## 2 Binning the data

Points are assigned to the bin they fall into based on the nearest centroid. If a point is equidistant from multiple centroids, it is assigned to the centroid with the lowest hexagonal bin ID.

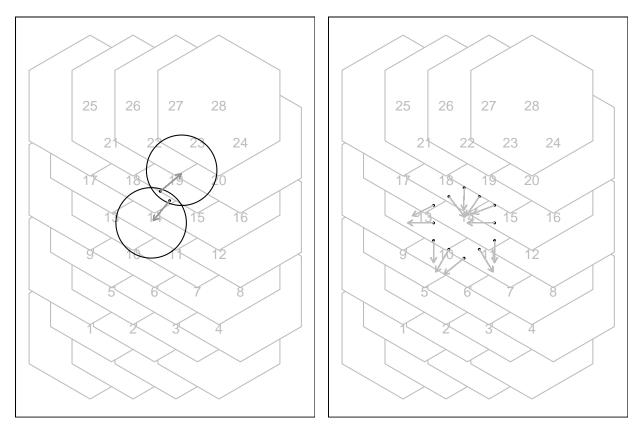

Figure 2: Binning the data. Points are assigned to the nearest centroid. If a point is equidistant from multiple centroids, assigned to the lowest centroid.

## 3 Area of a hexagon

The area of a hexagon is defined as  $A = \frac{3\sqrt{3}}{2}l^2$ , where l is the side length of the hexagon. l can be computed using  $a_1$  and  $a_2$ .

By pythagorean theorem,

$$\begin{split} l^2 &= (\frac{a_1}{2})^2 + (\frac{a_2-l}{2})^2 \\ l^2 &- (\frac{a_2-l}{2})^2 = (\frac{a_1}{2})^2 \\ [l &- (\frac{a_2-l}{2})][l + (\frac{a_2-l}{2})] = (\frac{a_1}{2})^2 \end{split}$$

$$3l^2 + 2la_2 - (a_1^2 + a_2^2) = 0$$

$$l = \frac{-2a_2 \pm \sqrt{4a_2^2 - 24[-(a_1^2 + a_2^2)]}}{6}$$
 
$$l = \frac{-a_2 \pm \sqrt{a_2^2 - 6[-(a_1^2 + a_2^2)]}}{3}$$
